Which jobs and applications need management attention right now?

Job Recruitment Health
The recruitment pipeline currently includes 3 stalled jobs and 4 jobs identified as at risk. Stalled jobs have limited recruitment activity and no meaningful progression, while at-risk jobs continue to receive applications but are converting candidates into hires at a low rate. Together, these two categories help distinguish between jobs that lack candidate demand and jobs where the recruitment process may be struggling to convert available demand into successful hires.

Highest Conversion Risk
Machine Learning Engineer represents the most significant conversion concern among the jobs currently flagged as at risk. The position has received 49 applications but has achieved a hiring rate of only 4.08%. This indicates that candidate volume alone is not producing successful recruitment outcomes, and may warrant further investigation into candidate quality, job requirements, screening criteria, or the recruitment process itself.

Applications Awaiting Movement
Recruitment delays are also visible at the individual application level. Hira Khan's application for the DevOps Engineer role has remained without movement for 137 days, making it the longest inactive application in the current on-hold backlog. Monitoring aging applications like this one helps prevent candidates from sitting unresolved for extended periods.

Recruitment Priority
This combined analysis helps prioritize recruitment attention across two levels: job-level performance and application-level delays. Jobs with weak candidate demand call for a different response than jobs receiving high application volume but poor conversion, while aging on-hold applications point to individual cases that need direct follow-up.
